

Capital.com Public API - Positions & Deal Confirmation

Part 3 for CapitalDemoBroker / Codex

Developer reference prepared from the current official Capital.com Public API 1.0.0 documentation. It focuses on the exact contracts needed for position creation, confirmation, recovery, reading, protection updates and closing.

1. Critical two-step execution rule

POST /positions returns a dealReference, but an HTTP-success response is not proof that the position was successfully opened. Capital.com explicitly requires the final state to be checked with GET /confirms/{dealReference}. This is the key rule for avoiding blind duplicate trading after an uncertain network result.

2. Create position

POST /api/v1/positions

Headers:

CST: REDACTED_CST

X-SECURITY-TOKEN: REDACTED_SECURITY_TOKEN

Content-Type: application/json

DEMO:

https://demo-api-capital.backend-capital.com/api/v1/positions

Required body fields:

direction : BUY | SELL

epic : instrument epic

size : number

Optional protection fields:

guaranteedStop

trailingStop

stopLevel

stopDistance

stopAmount

profitLevel

profitDistance

profitAmount

Field	Required	Important rule
direction	YES	BUY or SELL
epic	YES	Exact broker epic
size	YES	Deal size
guaranteedStop	NO	Default false; incompatible with trailingStop; unavailable with hedgingMode
trailingStop	NO	Default false; requires stopDistance; incompatible with guaranteedStop
stopLevel	NO	Absolute SL trigger price
stopDistance	NO	Distance to SL; required for trailingStop
stopAmount	NO	Loss amount based protection
profitLevel	NO	Absolute TP trigger price
profitDistance	NO	Distance to TP
profitAmount	NO	Profit amount based protection

Example structure:

```
{
  "epic": "SILVER",
  "direction": "BUY",
  "size": 1,
  "guaranteedStop": true,
```

```

    "stopLevel": 20,
    "profitLevel": 27
  }

```

Success response:

```

{
  "dealReference": "o_98c0de50-9cd5-4481-8d81-890c525eeb49"
}

```

Capital.com notes that position creation first creates an order; the returned dealReference has an **o_** prefix in the documented example.

For the project's direction mapping: LONG maps to BUY and SHORT maps to SELL.

3. Deal confirmation

```
GET /api/v1/confirm/{dealReference}
```

Headers:

CST: REDACTED_CST

X-SECURITY-TOKEN: REDACTED_SECURITY_TOKEN

DEMO:

```
https://demo-api-capital.backend-capital.com/api/v1/confirm/{dealReference}
```

The confirmation response is the broker-side source of truth for whether the requested operation was accepted and what permanent deal IDs were affected.

Documented confirmation fields include:

```

{
  "date": "...",
  "status": "OPEN",
  "dealStatus": "ACCEPTED",
  "epic": "SILVER",
  "dealReference": "o_...",
  "dealId": "...",
  "affectedDeals": [
    {
      "dealId": "...",
      "status": "OPENED"
    }
  ],
  "level": 24.285,
  "size": 1,
  "direction": "BUY",
  "guaranteedStop": false,
  "trailingStop": false
}

```

The documentation states that multiple positions can be opened at once and these are represented in affectedDeals. Therefore CapitalDemoBroker must not assume one request always maps to exactly one affected permanent deal ID.

4. Recovery / retry implication

- If POST /positions returns a dealReference, persist it before treating the operation as complete.
- Poll/query GET /confirm/{dealReference} and normalize dealStatus, status, level, size, direction, dealId and affectedDeals.
- Do not equate HTTP 200 from POST /positions with a filled/open position.
- If a network timeout leaves it unknown whether POST /positions reached Capital.com and no dealReference was received, the public contract shown here does not provide a documented client-generated idempotency key. Do not invent safe replay semantics.
- After an ambiguous trade outcome, Recovery should reconcile broker positions/history rather than blindly submit a duplicate market order.

5. Get all open positions

GET /api/v1/positions

DEMO:

<https://demo-api-capital.backend-capital.com/api/v1/positions>

Headers:

CST: REDACTED_CST

X-SECURITY-TOKEN: REDACTED_SECURITY_TOKEN

Each list item contains a position object and associated market snapshot. Documented position fields include contractSize, createdAt, createdAtUTC, dealId, dealReference, workingOrderId, size, leverage, upl, direction, level, currency and guaranteedStop.

The associated market object includes epic plus current bid/offer and marketStatus, allowing reconciliation of an open position with the exact instrument.

6. Get one position

GET /api/v1/positions/{dealId}

dealId = permanent deal reference for a confirmed trade

Responses documented:

200 OK

404 Not Found

7. Update Stop Loss / Take Profit

PUT /api/v1/positions/{dealId}

Optional body fields:

guaranteedStop

trailingStop

stopLevel

stopDistance

stopAmount

profitLevel

profitDistance

profitAmount

Example structure:

```
{
  "guaranteedStop": true,
  "stopDistance": 3,
  "profitAmount": 2
}
```

Success:

```
{
  "dealReference": "p_..."
}
```

The update endpoint accepts protection fields as optional parameters and returns another dealReference. The public section does not explicitly document, in the parameter table itself, a separate DELETE-SL or DELETE-TP endpoint or a definitive null/zero omission rule for removal. Therefore CapitalDemoBroker must not guess how to remove a single protection level; that behavior should be verified separately before implementing remove_sl/remove_tp.

8. Close position

DELETE /api/v1/positions/{dealId}

Headers:

CST: REDACTED_CST

X-SECURITY-TOKEN: REDACTED_SECURITY_TOKEN

DEMO:

`https://demo-api-capital.backend-capital.com/api/v1/positions/{dealId}`

```
Success:
{
  "dealReference": "p_..."
}
```

The current documented REST close contract is DELETE by permanent dealId. The endpoint shown has no request body for requested close size, so this documentation does not establish partial-close semantics through this endpoint. Do not invent a partial-close request body or opposite-direction close trade.

9. Hedging requirement

Capital.com states that the active account's trading mode is available through GET /accounts/preferences. The hedgingMode field indicates whether hedging is engaged and can be changed with PUT /accounts/preferences. For a strategy requiring simultaneous LONG and SHORT on the same epic, CapitalDemoBroker should verify hedgingMode before starting a cycle.

Guaranteed stops cannot be used when hedgingMode is true according to the documented create/update position constraints.

10. What the position API confirms and what remains unresolved

Confirmed	Do not assume
LONG -> BUY; SHORT -> SELL	That HTTP 200 means the position opened
POST /positions returns dealReference	That a missing response means the trade failed
GET /confirms/{dealReference} gives final confirmation data	That POST /positions is idempotent
Permanent open positions use dealId	That one confirmation always affects one position
GET /positions reconciles open broker state	That partial close is supported by DELETE /positions/{dealId}
PUT /positions/{dealId} updates SL/TP-related fields	How to remove only SL or only TP until explicitly verified
hedgingMode is an account preference	That hedging is enabled on a particular account without checking it

11. Suggested BrokerGateway mapping

- open_position(...) -> POST /positions -> dealReference -> GET /confirms/{dealReference}
- confirmation_for(dealReference) -> GET /confirms/{dealReference}
- list_positions() -> GET /positions
- get_position(dealId) -> GET /positions/{dealId}
- update_position_protection(dealId, ...) -> PUT /positions/{dealId} -> confirm/reconcile
- close_position(dealId) -> DELETE /positions/{dealId} -> dealReference -> confirmation/reconciliation
- preflight_hedging() -> GET /accounts/preferences and require hedgingMode=true for dual-sided cycles
